Spring 2010
1. Multiple Integrals
   - CSR in $n$-D
   - Non-Rectangular Domains

2. Improper Integrals
   - Calculus Treasures
   - Taylor Expansions... Surprise!
The World is not One-Dimensional

Very few interesting problems are one-dimensional, so we need integration schemes for multiple integrals, i.e.

\[ I = \int \int_R f(x, y) \, dx \, dy, \]

where \( R = \{(x, y) : x \in [a, b], y \in [c, d]\} \).

**Good News:** The integration techniques we have developed previously can be adopted for multi-dimensional integration in a straight-forward way.

Composite Simpson’s Rule (CSR) is our favorite integration scheme; we discuss multi-dimensional integration in that context.
Multi-Dimensional Composite Simpson’s Rule

We divide the $x$-range $[a, b]$ into an even number $n_x$ of sub-intervals with nodes spaced $h_x = (b - a)/n_x$ apart, and the $y$-range $[c, d]$ into an even number $n_y$ of sub-intervals with nodes spaced $h_y = (d - c)/n_y$ apart.

We write

$$I = \iiint_R f(x, y) \, dx \, dy = \int_{a}^{b} \left[ \int_{c}^{d} f(x, y) \, dy \right] \, dx,$$

and first apply CSR to approximate the integration in $y$ — treating $x$ as a constant.
Composite Simpson’s Rule in the y-coordinate

Let \( y_j = c + jh_y, \ j = 0, 1, \ldots, n_y \), then

\[
\int_c^d f(x, y) \, dy = \frac{h_y}{3} \left[ f(x, y_0) - f(x, y_n) + \sum_{j=1}^{n_y/2} [2f(x, y_{2j}) + 4f(x, y_{2j-1})] \right] \\
- \frac{(d - c)h_y^4}{180} \cdot \frac{\partial^4 f(x, \mu_y)}{\partial y^4},
\]

for some \( \mu_y \in [c, d] \).
Multiple Integrals
Improper Integrals
CSR in $n$-D
Non-Rectangular Domains

Composite Simpson’s Rule in the $y$-coordinate

1. Let $y_j = c + jh_y$, $j = 0, 1, \ldots, n_y$, then

$$
\int_{c}^{d} f(x, y) \, dy = \frac{h_y}{3} \left[ f(x, y_0) - f(x, y_n) + \sum_{j=1}^{n_y/2} [2f(x, y_{2j}) + 4f(x, y_{2j-1})] \right]
- \frac{(d - c)h_y^4}{180} \cdot \frac{\partial^4 f(x, \mu_y)}{\partial y^4},
$$

for some $\mu_y \in [c, d]$.

2. Then we apply the integral in the $x$–coordinate...

$$
\int_{a}^{b} \int_{c}^{d} f(x, y) \, dy \, dx = \frac{h_y}{3} \left[ \int_{a}^{b} f(x, y_0) \, dx - \int_{a}^{b} f(x, y_n) \, dx 
+ \sum_{j=1}^{n_y/2} \left[ 2\int_{a}^{b} f(x, y_{2j}) \, dx + 4\int_{a}^{b} f(x, y_{2j-1}) \, dx \right] \right]
- \frac{(d - c)h_y^4}{180} \int_{a}^{b} \frac{\partial^4 f(x, \mu_y)}{\partial y^4} \, dx,
$$

Joe Mahaffy, <mahaffy@math.sdsu.edu>
Now, we “simply” apply CSR in the $x$-coordinate, for each integral in the expression...
Apply Composite Simpson’s Rule in the $x$-coordinate

Now, we “simply” apply CSR in the $x$-coordinate, for each integral in the expression...

$$
\int_a^b \int_c^d f(x, y) \, dy \, dx \approx \frac{h_x h_y}{9} \left\{ \left[ f(x_0, y_0) - f(x_n, y_0) + \sum_{i=1}^{n_x/2} \left( 2f(x_{2i}, y_0) + 4f(x_{2i-1}, y_0) \right) \right] \\
- \left[ f(x_0, y_n) - f(x_n, y_n) + \sum_{i=1}^{n_x/2} \left( 2f(x_{2i}, y_n) + 4f(x_{2i-1}, y_n) \right) \right] \\
+ \sum_{j=1}^{n_y/2} \left[ 2f(x_0, y_{2j}) - f(x_n, y_{2j}) + \sum_{i=1}^{n_x/2} \left( 2f(x_{2i}, y_{2j}) + 4f(x_{2i-1}, y_{2j}) \right) \right] \\
+ 4 \left[ f(x_0, y_{2j-1}) - f(x_n, y_{2j-1}) + \sum_{i=1}^{n_x/2} \left( 2f(x_{2i}, y_{2j-1}) + 4f(x_{2i-1}, y_{2j-1}) \right) \right] \right\}
$$

This looks somewhat painful, but do not despair!!! [First, a peek at the error...]
The error for the approximation is

\[ E = -\frac{(b - a)(d - c)}{180} \left[ h_x^4 \frac{\partial^4 f}{\partial x^4}(\nu_x, \mu_x) + h_y^4 \frac{\partial^4 f}{\partial y^4}(\nu_y, \mu_y) \right] \]

for some \((\nu_x, \mu_x), (\nu_y, \mu_y) \in R = [a, b] \times [c, d]\).

“Derivation of the error is left as an exercise for the interested reader...”
Building 2-D CSR in a Comprehensible Way?

Consider the tensor product of the $x$- and $y$-stencils for CSR with 2 sub-intervals:

\[
\frac{h_x}{3} \begin{array}{c} 1 \ 4 \ 2 \ 4 \ 1 \end{array} \otimes \frac{h_y}{3} \begin{array}{c} 1 \\ 4 \\ 2 \\ 4 \\ 1 \end{array} = \]
Consider the tensor product of the $x$- and $y$-stencils for CSR with 2 sub-intervals:

$$\frac{h_x}{3} \begin{array}{c} 1 \end{array} \begin{array}{cccc} 4 & 2 & 4 & 1 \end{array} \otimes \frac{h_y}{3} \begin{array}{c} 1 \end{array} \begin{array}{cccc} 2 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 1 \end{array} = \frac{h_x h_y}{9} \begin{array}{cccc} 1 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 2 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 1 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 16 \end{array} \begin{array}{cccc} 8 \end{array} \begin{array}{cccc} 16 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 2 \end{array} \begin{array}{cccc} 8 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 8 \end{array} \begin{array}{cccc} 2 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 16 \end{array} \begin{array}{cccc} 8 \end{array} \begin{array}{cccc} 16 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 1 \end{array} \begin{array}{cccc} 1 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 2 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 1 \end{array} \begin{array}{cccc} 1 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 2 \end{array} \begin{array}{cccc} 4 \end{array} \begin{array}{cccc} 1 \end{array}$$
Building 2-D CSR in a Comprehensible Way?

Consider the tensor product of the $x$- and $y$-stencils for CSR with 2 sub-intervals:

\[
\begin{array}{cccc}
\frac{h_x}{3} & 1 & 4 & 2 & 4 & 1 \\
\frac{h_y}{3} & 1 & 4 & 2 & 4 & 1 \\
\end{array}
\otimes
\begin{array}{cccc}
1 & 4 & 2 & 4 & 1 \\
4 & 16 & 8 & 16 & 16 & 4 \\
4 & 16 & 8 & 16 & 16 & 4 \\
1 & 4 & 2 & 4 & 1 \\
\end{array}
= \frac{h_xh_y}{9}
\]

Evaluate the function at the corresponding points, multiply by the above weights, and sum \(\Rightarrow\) 2-D CSR.
Building 2-D CSR in a Comprehensible Way? — Example

\[
\frac{9}{h_x h_y} \int_{x_0}^{x_4} \int_{y_0}^{y_4} f(x, y) \, dx \, dy \approx \\
1 \left[ f(x_0, y_0) + 4f(x_1, y_0) + 2f(x_2, y_0) + 4f(x_3, y_0) + f(x_4, y_0) \right] + \\
4 \left[ f(x_0, y_1) + 4f(x_1, y_1) + 2f(x_2, y_1) + 4f(x_3, y_1) + f(x_4, y_1) \right] + \\
2 \left[ f(x_0, y_2) + 4f(x_1, y_2) + 2f(x_2, y_2) + 4f(x_3, y_2) + f(x_4, y_2) \right] + \\
4 \left[ f(x_0, y_3) + 4f(x_1, y_3) + 2f(x_2, y_3) + 4f(x_3, y_3) + f(x_4, y_3) \right] + \\
1 \left[ f(x_0, y_4) + 4f(x_1, y_4) + 2f(x_2, y_4) + 4f(x_3, y_4) + f(x_4, y_4) \right]
\]

\[ h_x = \frac{x_4 - x_0}{4}, \quad h_y = \frac{y_4 - y_0}{4}. \]
Using the same strategy, we can build a 3-D CSR-scheme

\[ \text{CSR}_{xyz} = \text{CSR}_x \otimes \text{CSR}_y \otimes \text{CSR}_z. \]
Using the same strategy, we can build a 3-D CSR-scheme

$$\text{CSR}_{xyz} = \text{CSR}_x \otimes \text{CSR}_y \otimes \text{CSR}_z.$$ 

There’s nothing unique about the usage of CSR. The same idea can be used to build higher dimensional Gaussian Quadrature schemes. If we have the stencils for the one-dimensional (Composite) Gaussian Quadrature schemes in the $x$-, $y$- and $z$-directions ($\text{GQ}_x$, $\text{GQ}_y$, $\text{GQ}_z$):

$$\text{GQ}_{xyz} = \text{GQ}_x \otimes \text{GQ}_y \otimes \text{GQ}_z.$$
Building Higher-Dimensional Schemes

Using the same strategy, we can build a 3-D CSR-scheme

\[ \text{CSR}_{xyz} = \text{CSR}_x \otimes \text{CSR}_y \otimes \text{CSR}_z. \]

There's nothing unique about the usage of CSR. The same idea can be used to build higher dimensional Gaussian Quadrature schemes. If we have the stencils for the one-dimensional (Composite) Gaussian Quadrature schemes in the \(x\)-, \(y\)- and \(z\)-directions (\(GQ_x\), \(GQ_y\), \(GQ_z\)):

\[ \text{GQ}_{xyz} = \text{GQ}_x \otimes \text{GQ}_y \otimes \text{GQ}_z. \]

If you’re really twisted you could use different schemes in the different coordinate directions, \(i.e.\)

\[ \text{NUMINT}_{xyz} = \text{CSR}_x \otimes \text{GQ}_y \otimes \text{Romberg}_z. \]

Needless to say, the error terms would get really “interesting.”
The integration schemes we have discussed so far only works for rectangular regions \([a, b] \times [c, d]\)...

In calculus we compute integrals of this form:

\[
\int_a^b \int_{c(x)}^{d(x)} f(x, y) \, dy \, dx
\]

We can modify our integration schemes to deal with this type of integrals.
In order to numerically compute an integral of this type

\[
\int_{a}^{b} \int_{c(x)}^{d(x)} f(x, y) \, dy \, dx
\]

we are going to use CSR with a fixed step size \( h_x = (b - a)/n_x \) in the \( x \)-direction, and variable step size \( h_y = (d(x) - c(x))/n_y \) in the \( y \)-direction.

Joe Mahaffy, \(<mahaffy@math.sdsu.edu>\)
Variable Integration Limits — Example

For simplicity we apply straight-up one-step SR to

$$\int_a^b \int_{c(x)}^{d(x)} f(x, y) \, dy \, dx$$

and get

$$\int_a^b \int_{c(x)}^{d(x)} f(x, y) \, dy \, dx \approx \frac{h_x}{3} \left\{ \frac{d(x_0) - c(x_0)}{6} \left[ f(x_0, c(x_0)) + 4f(x_0, \frac{c(x_0) + d(x_0)}{2}) + f(x_0, d(x_0)) \right] + \frac{4(d(x_1) - c(x_1))}{6} \left[ f(x_1, c(x_1)) + 4f(x_1, \frac{c(x_1) + d(x_1)}{2}) + f(x_1, d(x_1)) \right] + \frac{d(x_2) - c(x_2)}{6} \left[ f(x_2, c(x_2)) + 4f(x_2, \frac{c(x_2) + d(x_2)}{2}) + f(x_2, d(x_2)) \right] \right\},$$

where $x_0 = a$, $x_1 = \frac{a + b}{2}$, $x_2 = b$. 
We can imagine how to extend to multiple dimensions, *i.e.*

\[
\int_a^b \int_{c(x)}^{d(x)} \int_{e(x,y)}^{f(x,y)} g(x, y, z) \, dz \, dy \, dx.
\]

Again, there nothing special about Simpson’s Rule — we can attack variable integration limits with Gaussian Quadrature, Trapezoidal Rule, or Boole’s Rule...

Note that there is nothing stopping us from using adaptive schemes to find the integrals... but the complexity of the code grows!
Algorithm: Variable Limits Double Integral using CSR

Improper Integrals — Introduction

“Improper” integrals:

[1] Integrals over infinite intervals

\[ \int_a^\infty f(x) \, dx. \]

[2] Integrals with unbounded functions

\[ \int_a^b \frac{f(x)}{(x - a)^p} \, dx. \]
“Improper” integrals:

[1] Integrals over infinite intervals

\[ \int_{a}^{\infty} f(x) \, dx. \]

[2] Integrals with unbounded functions

\[ \int_{a}^{b} \frac{f(x)}{(x - a)^p} \, dx. \]

**Note:** We can always transform [1] → [2]

\[ \int_{a}^{\infty} f(x) \, dx = \left\{ \begin{array}{l} t = x^{-1} \\ dt = -x^{-2} \, dx \end{array} \right\} = \int_{1/a}^{0} -t^{-2} f(t^{-1}) \, dt \]
The integral

\[ \int_{a}^{b} \frac{dx}{(x - a)^p} \]

converges if and only if \( p \in (-\infty, 1) \), and

\[ \int_{a}^{b} \frac{dx}{(x - a)^p} = \frac{(b - a)^{1-p}}{1 - p}. \]
The integral
\[ \int_a^b \frac{dx}{(x - a)^p} \]
converges if and only if \( p \in (-\infty, 1) \), and
\[ \int_a^b \frac{dx}{(x - a)^p} = \frac{(b - a)^{1-p}}{1 - p}. \]

If \( f(x) \) can be written on the form
\[ f(x) = \frac{g(x)}{(x - a)^p}, \quad p \in (-\infty, 1), \quad g \in C[a, b] \]
then the improper integral
\[ \int_a^b f(x) \, dx, \text{ exists.} \]
Assuming that \( g \in C^{d+1}[a, b] \), for some \( d \in \mathbb{Z}^+ \), the Taylor polynomial of degree \( d \) is

\[
P_d(x) = \sum_{k=0}^{d} \frac{g^{(k)}(a)(x - a)^k}{k!}.
\]
Assuming that \( g \in C^{d+1}[a, b] \), for some \( d \in \mathbb{Z}^+ \), the Taylor polynomial of degree \( d \) is

\[
P_d(x) = \sum_{k=0}^{d} \frac{g^{(k)}(a)(x - a)^k}{k!}.
\]

We can now write

\[
\int_{a}^{b} f(x) \, dx = \int_{a}^{b} \frac{g(x) - P_d(x)}{(x - a)^p} \, dx + \int_{a}^{b} \frac{P_d(x)}{(x - a)^p} \, dx,
\]
Splitting the Integrand using Taylor Expansions

Assuming that \( g \in C^{d+1}[a, b] \), for some \( d \in \mathbb{Z}^+ \), the Taylor polynomial of degree \( d \) is

\[
    P_d(x) = \sum_{k=0}^{d} \frac{g^{(k)}(a)(x - a)^k}{k!}.
\]

We can now write

\[
    \int_a^b f(x) \, dx = \int_a^b \frac{g(x) - P_d(x)}{(x - a)^p} \, dx + \int_a^b \frac{P_d(x)}{(x - a)^p} \, dx,
\]

where the last integral is easy to find, since \( P_d(x) \) is a polynomial:

\[
    \sum_{k=0}^{d} \int_a^b \frac{g^{(k)}(a)}{k!} (x - a)^{k-p} \, dx = \sum_{k=0}^{d} \frac{g^{(k)}(a)}{k!(k + 1 - p)} (b - a)^{k+1-p}
\]
If we let
\[
\int_{a}^{b} f(x) \, dx \approx \sum_{k=0}^{d} \frac{g^{(k)}(a)}{k!(k + 1 - p)} (b - a)^{k+1-p},
\]
then the approximation error is bounded by:
\[
\int_{a}^{b} g(x) - P_{d}(x) \left(\frac{x}{x - a}\right)^{p} \, dx = \int_{a}^{b} \frac{R_{d}(x)}{(x - a)^{p}} \, dx = \int_{a}^{b} \frac{g^{(d+1)}(\xi(x))(x - a)^{d+1}}{(k + 1)! (x - a)^{p}} \, dx
\]
\[
\leq \frac{1}{(k + 1)!} \max_{x \in [a, b]} |g^{(d+1)}(x)| \int_{a}^{b} (x - a)^{d+1-p} \, dx
\]
\[
= \frac{g^{(d+1)}(\xi)}{(k + 1)! (d + 2 - p)} (b - a)^{d+2-p}.
\]
If we let
\[ \int_a^b f(x) \, dx \approx \sum_{k=0}^{d} \frac{g^{(k)}(a)}{k!(k+1-p)} (b-a)^{k+1-p}, \]
then the approximation error is bounded by:
\[ \int_a^b \frac{g(x) - P_d(x)}{(x-a)^p} \, dx = \int_a^b \frac{R_d(x)}{(x-a)^p} \, dx = \int_a^b \frac{g^{(d+1)}(\xi(x))(x-a)^{d+1}}{(k+1)!(x-a)^p} \, dx \]
\[ \leq \frac{1}{(k+1)!} \max_{x \in [a,b]} |g^{(d+1)}(x)| \int_a^b (x-a)^{d+1-p} \, dx \]
\[ = \frac{g^{(d+1)}(\xi)}{(k+1)!(d+2-p)} (b-a)^{d+2-p}. \]

What if we want to do better?
Numerical Approximation of the Remainder Term

To get a more accurate approximation to the integral, we compute the numerical approximation of the remainder term:

$$\int_{a}^{b} \frac{g(x) - P_d(x)}{(x - a)^p} \, dx.$$
To get a more accurate approximation to the integral, we compute the numerical approximation of the remainder term:

\[ \int_a^b \frac{g(x) - P_d(x)}{(x - a)^p} \, dx. \]

**Define:** (Remove the singularity)

\[
G(x) = \begin{cases} 
\frac{g(x) - P_d(x)}{(x - a)^p} & x \in (a, b] \\
0 & x = a.
\end{cases}
\]
Numerical Approximation of the Remainder Term

To get a more accurate approximation to the integral, we compute the numerical approximation of the remainder term:

$$\int_{a}^{b} \frac{g(x) - P_d(x)}{(x - a)^p} \, dx.$$ 

**Define:** (Remove the singularity)

$$G(x) = \begin{cases} 
\frac{g(x) - P_d(x)}{(x - a)^p} & x \in (a, b] \\
0 & x = a. 
\end{cases}$$

**Apply:** Composite Simpson’s Rule

$$\int_{a}^{b} G(x) \, dx \approx \frac{h}{3} \left[ G(x_0) - G(x_n) + \sum_{j=1}^{n/2} \left( 4G(x_{2j-1}) + 2G(x_{2j}) \right) \right].$$
Numerical Approximation of the Remainder Term

To get a more accurate approximation to the integral, we compute the numerical approximation of the remainder term:

$$\int_a^b \frac{g(x) - P_d(x)}{(x - a)^p} \, dx.$$

**Define:** (Remove the singularity)

$$G(x) = \begin{cases} 
\frac{g(x) - P_d(x)}{(x - a)^p} & x \in (a, b] \\
0 & x = a.
\end{cases}$$

**Apply:** Composite Simpson’s Rule

$$\int_a^b G(x) \, dx \approx \frac{h}{3} \left[ G(x_0) - G(x_n) + \sum_{j=1}^{n/2} \left[ 4G(x_{2j-1}) + 2G(x_{2j}) \right] \right].$$

Add the CSR-approximation to

$$\sum_{k=0}^{d} \frac{g^{(k)}(a)}{k!(k+1-p)} (b - a)^{k+1-p}.$$
We want to compute
\[ \int_0^1 \frac{e^x}{x^{1/2}} \, dx. \]

The fourth order Taylor polynomial is
\[ P_4(x) = 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24}, \]
Example #1

We want to compute

\[
\int_{0}^{1} \frac{e^x}{x^{1/2}} \, dx.
\]

The fourth order Taylor polynomial is

\[
P_4(x) = 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24},
\]

so

\[
\int_{0}^{1} \frac{P_4(x)}{x^{1/2}} \, dx = \int_{0}^{1} x^{-1/2} + x^{1/2} + \frac{x^{3/2}}{2} + \frac{x^{5/2}}{6} + \frac{x^{7/2}}{24} \, dx
\]

\[
= \frac{2}{1} + \frac{2}{3} + \frac{2}{2 \cdot 5} + \frac{2}{6 \cdot 7} + \frac{2}{24 \cdot 9} \approx 2.923544974
\]
Example #1

Next, we apply CSR with $h = 1/4$ to $\int_0^1 G(x) \, dx$, where

$$G(x) = \begin{cases} 
\frac{e^x - P_4(x)}{x^{1/2}} & x \in (0, 1] \\
0 & x = 0.
\end{cases}$$
Example#1

Next, we apply CSR with $h = 1/4$ to $\int_0^1 G(x) \, dx$, where

$$G(x) = \begin{cases} 
\frac{e^x - P_4(x)}{x^{1/2}} & x \in (0, 1] \\
0 & x = 0.
\end{cases}$$

$$\int_0^1 G(x) \, dx \approx \frac{1}{4 \cdot 3} \left[ 0 + 4 \cdot 0.0000170 + 2 \cdot 0.00413 + 4 \cdot 0.0026026 + 0.0099485 \right] = 0.0017691.$$
Example #1

Next, we apply CSR with $h = 1/4$ to $\int_0^1 G(x) \, dx$, where

$$G(x) = \begin{cases} \frac{e^x - P_4(x)}{x^{1/2}} & x \in (0, 1] \\ 0 & x = 0. \end{cases}$$

$$\int_0^1 G(x) \, dx \approx \frac{1}{4 \cdot 3} \left[ 0 + 4 \cdot 0.0000170 + 2 \cdot 0.00413 + 4 \cdot 0.0026026 \\ + 0.0099485 \right] = 0.0017691.$$  

Hence,

Result

$$\int_0^1 \frac{e^x}{x^{1/2}} \, dx \approx 2.923544974 + 0.0017691 = 2.9253141$$
Since $|G^{(4)}(x)| < 1$ on $(0, 1]$, the error from CSR is bounded by
\[
\frac{1}{180} \cdot \frac{1}{4^4} = 0.0000217.
\]
Example #1

Since $|G^{(4)}(x)| < 1$ on $(0, 1]$, the error from CSR is bounded by

$$\frac{1}{180} \cdot \frac{1}{4^4} = 0.0000217.$$ 

The error bound for the Taylor-only approximation is bounded by

$$\frac{1}{5! \cdot 5.5} = 0.00151515.$$
Example #1

Since \(|G^{(4)}(x)| < 1\) on \((0, 1]\), the error from CSR is bounded by

\[
\frac{1}{180} \cdot \frac{1}{4^4} = 0.0000217.
\]

The error bound for the Taylor-only approximation is bounded by

\[
\frac{1}{5! \cdot 5.5} = 0.00151515
\]

If, instead of adding the CSR-approximation of \(\int G(x) \, dx\), we used \(P_5(x)\), the error bound for that Taylor-only approximation would be

\[
\frac{1}{6! \cdot 6.5} = 0.00021044.
\]
Example #1

Since $|G^{(4)}(x)| < 1$ on $(0, 1]$, the error from CSR is bounded by

$$\frac{1}{180} \cdot \frac{1}{4^4} = 0.0000217.$$  

The error bound for the Taylor-only approximation is bounded by

$$\frac{1}{5! \cdot 5.5} = 0.00151515.$$  

If, instead of adding the CSR-approximation of $\int G(x) \, dx$, we used $P_5(x)$, the error bound for that Taylor-only approximation would be

$$\frac{1}{6! \cdot 6.5} = 0.00021044.$$  

The $P_6(x)$-only-error is comparable with the $P_4(x) +$ CSR-error:

$$\frac{1}{7! \cdot 7.5} = 0.000026455.$$
We are going to approximate the integral
\[
\int_{1}^{\infty} \frac{1}{x^{3/2}} \sin \left( \frac{1}{x} \right) \, dx.
\]
We are going to approximate the integral

\[ \int_{1}^{\infty} \frac{1}{x^{3/2}} \sin \left( \frac{1}{x} \right) \, dx. \]

A quick change of variables \( t = x^{-1} \) gives us

\[ \int_{0}^{1} t^{-1/2} \sin(t) \, dt. \]
We are going to approximate the integral
\[
\int_{1}^{\infty} \frac{1}{x^{3/2}} \sin \left( \frac{1}{x} \right) \, dx.
\]
A quick change of variables \( t = x^{-1} \) gives us
\[
\int_{0}^{1} t^{-1/2} \sin(t) \, dt.
\]

The sixth Taylor polynomial \( P_6(t) \) for \( \sin(t) \) about \( t = 0 \) is
\[
P_6(t) = t - \frac{1}{6} t^3 + \frac{1}{120} t^5, \quad |R_6(t)| \leq \frac{1}{7!} = 0.00019841.
\]
Example #2

We are going to approximate the integral

$$\int_1^\infty \frac{1}{x^{3/2}} \sin \left( \frac{1}{x} \right) \, dx.$$  

A quick change of variables $t = x^{-1}$ gives us

$$\int_0^1 t^{-1/2} \sin(t) \, dt.$$  

The sixth Taylor polynomial $P_6(t)$ for $\sin(t)$ about $t = 0$ is

$$P_6(t) = t - \frac{1}{6} t^3 + \frac{1}{120} t^5, \quad |R_6(t)| \leq \frac{1}{7!} = 0.00019841$$

$$\int_0^1 t^{-1/2} P_6(t) \, dt = \int_0^1 t^{1/2} - \frac{1}{6} t^{5/2} + \frac{1}{120} t^{9/2} \, dt$$

$$= \frac{2}{3} - \frac{2}{7 \cdot 6} + \frac{2}{11 \cdot 120} = 0.62056277$$
Example #2

We define

\[ G(t) = \begin{cases} \frac{\sin(t) - P_6(t)}{t^{1/2}} & t \in (0, 1] \\ 0 & t = 0, \end{cases} \]

and apply CSR with \( h = 1/32 \) to \( \int_0^1 G(t) \, dt \) to get

**Result**

\[
\int_1^\infty \frac{1}{x^{3/2}} \sin \left( \frac{1}{x} \right) \, dx \\
\approx 0.62056277 - 0.0000261672790305 = 0.62053660 \ldots
\]

which is accurate to within \( \sim 10^{-8} \).
